The GOWEB System of Structured Documentation

This document describes a version of Don Knuth's and Silvio Levy's CWEB system, adapted to Go by Alexander Sychev. Bug reports, suggestions and comments are welcome, and should be sent to (santucco@gmail.com).

Introduction

The philosophy behind GOWEB is that programmers who want to provide the best possible documentation for their programs need two things simultaneously: a language like TEX for formatting, and a language like Go for programming. Neither type of language can provide the best documentation by itself. But when both are appropriately combined, we obtain a system that is much more useful than either language separately.

The structure of a software program may be thought of as a "web" that is made up of many interconnected pieces. To document such a program, we want to explain each individual part of the web and how it relates to its neighbors. The typographic tools provided by TEX give us an opportunity to explain the local structure of each part by making that structure visible, and the programming tools provided by Go make it possible for us to specify the algorithms formally and unambiguously. By combining the two, we can develop a style of programming that maximizes our ability to perceive the structure of a complex piece of software, and at the same time the documented programs can be mechanically translated into a working software system that matches the documentation.

The GOWEB system consists of two programs named GOWEAVE and GOTANGLE. When writing a GOWEB program the user keeps the Go code and the documentation in the same file, called the GOWEB file and generally named something.w. The command '`goweave something`' creates an output file something.tex, which can then be fed to TEX, yielding a "pretty printed" version of something.w that correctly handles typographic details like page layout and the use of indentation, italics, boldface, and mathematical symbols. The typeset output also includes extensive cross-index information that is gathered automatically. Similarly, if you run the command '`gotangle something`' you will get a Go file something.go, which can then be compiled to yield executable code.

Besides providing a documentation tool, GOWEB enhances the Go language by providing the ability to permute pieces of the program text, so that a large system can be understood entirely in terms of small sections and their local interrelationships. The GOTANGLE program is so named because it takes a given web and moves the sections from their web structure into the order required by Go; the advantage of programming in GOWEB is that the algorithms can be expressed in "untangled" form, with each section explained separately. The GOWEAVE program is so named because it takes a given web and intertwines the TEX and Go portions contained in each section, then it knits the whole fabric into a structured document. (Get it? Wow.) Perhaps there is some deep connection here with the fact that the German word for "weave" is "*webe*", and the corresponding Latin imperative is "*texe*"!

A user of GOWEB should be fairly familiar with the Go programming language. A minimal amount of acquaintance with TEX is also desirable, but in fact it can be acquired as one uses GOWEB, since straight text can be typeset in TEX with virtually no knowledge of that language. To someone familiar with both Go and TEX the amount of effort necessary to learn the commands of GOWEB is small.

Overview

Two kinds of material go into GOWEB files: TEX text and Go text. A programmer writing in GOWEB should be thinking both of the documentation and of the Go program being created; i.e., the programmer should be instinctively aware of the different actions that GOWEAVE and GOTANGLE will perform on the GOWEB file. TEX text is essentially copied without change by GOWEAVE, and it is entirely deleted by GOTANGLE; the TEX text is "pure documentation." Go text, on the other hand, is formatted by GOWEAVE and it is shuffled around by GOTANGLE, according to rules that will become clear later. For now the important point to keep in mind is that there are two kinds of text. Writing GOWEB programs is something like writing TEX documents, but with an additional "Go mode" that is added to TEX's horizontal mode, vertical mode, and math mode.

A GOWEB file is built up from units called *sections* that are more or less self-contained. Each section has three parts:

- A TEX part, containing explanatory material about what is going on in the section.
- A middle part, containing format definitions.

- A Go part, containing a piece of the program that GOTANGLE will produce. This Go code should ideally be about a dozen lines long, so that it is easily comprehensible as a unit and so that its structure is readily perceived.

The three parts of each section must appear in this order; i.e., the TEX commentary must come first, then the middle part, and finally the Go code. Any of the parts may be empty.

A section begins with either of the symbols '@␣' or '@*', where '␣' denotes a blank space. A section ends at the beginning of the next section (i.e., at the next '@␣' or '@*'), or at the end of the file, whichever comes first. The GOWEB file may also contain material that is not part of any section at all, namely the text (if any) that occurs before the first section. Such text is said to be "in limbo"; it is ignored by GOTANGLE and copied essentially verbatim by GOWEAVE, so its function is to provide any additional formatting instructions that may be desired in the TEX output. Indeed, it is customary to begin a GOWEB file with TEX code in limbo that loads special fonts, defines special macros, changes the page sizes, and/or produces a title page.

Sections are numbered consecutively, starting with 1. These numbers appear at the beginning of each section of the TEX documentation output by GOWEAVE, and they appear as bracketed comments at the beginning and end of the code generated by that section in the Go program output by GOTANGLE.

Section Names

Fortunately, you never mention these numbers yourself when you are writing in GOWEB. You just say '@␣' or '@*' at the beginning of each new section, and the numbers are supplied automatically by GOWEAVE and GOTANGLE. As far as you are concerned, a section has a *name* instead of a number; its name is specified by writing '@<' followed by TEX text followed by '@>'. When GOWEAVE outputs a section name, it replaces the '@<' and '@>' by angle brackets and inserts the section number in small type. Thus, when you read the output of GOWEAVE it is easy to locate any section that is referred to in another section.

For expository purposes, a section name should be a good description of the contents of that section; i.e., it should stand for the abstraction represented by the section. Then the section can be "plugged into" one or more other sections in such a way that unimportant details of its inner workings are suppressed. A section name therefore ought to be long enough to convey the necessary meaning.

Unfortunately, it is laborious to type such long names over and over again, and it is also difficult to specify a long name twice in exactly the same way so that GOWEAVE and GOTANGLE will be able to match the names to the sections. To ameliorate this situation, GOWEAVE and GOTANGLE let you abbreviate a section name, so long as the full name appears somewhere in the GOWEB file; you can type simply '@<α...@>', where α is any string that is a prefix of exactly one section name appearing in the file. For example, '@<Clear the arrays@>' can be abbreviated to '@<Clear...@>' if no other section name begins with the five letters 'Clear'. Elsewhere you might use the abbreviation '@<Clear t...@>', and so on.

Section names must otherwise match character for character, except that consecutive characters of white space (spaces, tab marks, newlines, and/or form feeds) are treated as equivalent to a single space, and such spaces are deleted at the beginning and end of the name. Thus, '@< Clear the arrays @>' will also match the name in the previous example. Spaces following the ellipsis in abbreviations are ignored as well, but not those before, so that '@<Clear t ...@>' would not match '@<Clear the arrays@>'.

What GOTANGLE Does

We have said that a section begins with '@␣' or '@*', but we didn't say how it gets divided up into a TEX part, a middle part, and a Go part. The middle part begins with the first appearance of '@f' in the section, and the Go part begins with the first appearance of '@c' or '@<section name@>='. In the latter case you are saying, in effect, that the section name stands for the Go text that follows. Alternatively, if the Go part begins with '@c' instead of a section name, the current section is said to be *unnamed*.

The construct '@<section name@>' can appear any number of times in the Go part of a section: Subsequent appearances indicate that a named section is being "used" rather than "defined." In other words, the Go code for the named section, presumably defined elsewhere, should be spliced in at this point in the Go program. Indeed, the main idea of GOTANGLE is to make a Go program out of individual sections, named and unnamed. The exact way in which this is done is this: The Go parts of unnamed sections are copied down, in order; this constitutes the first-order approximation to the text of the program. (There should be at least one unnamed section, otherwise there will be no program.) Then all section names that appear in the first-order approximation are replaced by the Go parts of the corresponding sections, and this substitution

process continues until no section names remain. All comments are removed, because the Go program is intended only for the eyes of the Go compiler.

If the same name has been given to more than one section, the Go text for that name is obtained by putting together all of the Go parts in the corresponding sections. This feature is useful, for example, in a section named 'Global variables', since one can then declare global variables in whatever sections those variables are introduced. When several sections have the same name, GOWEAVE assigns the first section number as the number corresponding to that name, and it inserts a note at the bottom of that section telling the reader to 'See also sections so-and-so'; this footnote gives the numbers of all the other sections having the same name as the present one. The Go text corresponding to a section is usually formatted by GOWEAVE so that the output has an equivalence sign in place of the equals sign in the GOWEB file; i.e., the output says '⟨ section name ⟩ ≡ Go text'. However, in the case of the second and subsequent appearances of a section with the same name, this '≡' sign is replaced by '+≡', as an indication that the following Go text is being appended to the Go text of another section.

As GOTANGLE enters and leaves sections, it inserts `//line` commentary into the Go output file. This means that when the compiler gives you error messages, or when you debug your program, the messages refer to line numbers in the GOWEB file, and not in the Go file. In most cases you can therefore forget about the Go file altogether.

What GOWEAVE Does

The general idea of GOWEAVE is to make a `.tex` file from the GOWEB file in the following way: The first line of the `.tex` file tells TEX to input a file with macros that define GOWEB's documentation conventions. The next lines of the file will be copied from whatever TEX text is in limbo before the first section. Then comes the output for each section in turn, possibly interspersed with end-of-page marks. Finally, GOWEAVE will generate a cross-reference index that lists each section number in which each Go identifier appears, and it will also generate an alphabetized list of the section names, as well as a table of contents that shows the page and section numbers for each "starred" section.

What is a "starred" section, you ask? A section that begins with '`@*`' instead of '`@␣`' is slightly special in that it denotes a new major group of sections. The '`@*`' should be followed by the title of this group, followed by a period. Such sections will always start on a new page in the TEX output, and the group title will appear as a running headline on all subsequent pages until the next starred section. The title will also appear in the table of contents, and in boldface type at the beginning of its section. Caution: Do not use TEX control sequences in such titles, unless you know that the `gowebmac` macros will do the right thing with them. The reason is that these titles are converted to uppercase when they appear as running heads, and they are converted to boldface when they appear at the beginning of their sections, and they are also written out to a table-of-contents file used for temporary storage while TEX is working; whatever control sequences you use must be meaningful in all three of these modes.

The TEX output produced by GOWEAVE for each section consists of the following: First comes the section number (e.g., '`\M123.`' at the beginning of section 123, except that '`\N`' appears in place of '`\M`' at the beginning of a starred section). Then comes the TEX part of the section, copied almost verbatim except as noted below. Then comes the middle part and the Go part, formatted so that there will be a little extra space between them if both are nonempty. The middle and Go parts are obtained by inserting a bunch of funny-looking TEX macros into the Go program; these macros handle typographic details about fonts and proper math spacing, as well as line breaks and indentation.

GO Code in TEX Text and Vice Versa

When you are typing TEX text, you will probably want to make frequent reference to variables and other quantities in your Go code, and you will want those variables to have the same typographic treatment when they appear in your text as when they appear in your program. Therefore the GOWEB language allows you to get the effect of Go editing within TEX text, if you place '`|`' marks before and after the Go material. For example, suppose you want to say something like this:

If *pa* is declared as '*pa* ∗**int**', the assignment *pa* = &*a*[0] makes *pa* point to the zeroth element of *a*.

The TEX text would look like this in your GOWEB file:

```
If |pa| is declared as '|pa *int|', the
assignment |pa=&a[0]| makes |pa| point to the zeroth element of |a|.
```

And GOWEAVE translates this into something you are glad you didn't have to type:

```
If \\{pa} is declared as '\{pa} ${}{*}\\&{int}$',
the assignment $\\{pa}\K{\AND}\|a[\T{0}]$
makes \\{pa} point to the zeroth element of \|a.
```

Incidentally, the cross-reference index that GOWEAVE would make, in the presence of a comment like this, would include the current section number as one of the index entries for *pa*, even though *pa* might not appear in the Go part of this section. Thus, the index covers references to identifiers in the explanatory comments as well as in the program itself; you will soon learn to appreciate this feature. However, the identifiers **int** and *a* would not be indexed, because GOWEAVE does not make index entries for reserved words or single-letter identifiers. Such identifiers are felt to be so ubiquitous that it would be pointless to mention every place where they occur.

Although a section begins with TEX text and ends with Go text, we have noted that the dividing line isn't sharp, since Go text can be included in TEX text if it is enclosed in '|...|'. Conversely, TEX text appears frequently within Go text, because everything in comments (i.e., between /* and */, or following //) is treated as TEX text. Likewise, the text of a section name consists of TEX text, but the construct @<section name@> as a whole is expected to be found in Go text; thus, one typically goes back and forth between the Go and TEX environments in a natural way, as in these examples:

```
if x==0 { @<Empty the |buffer| array@> }
... using the algorithm in |@<Empty the |buffer| array@>|.
```

The first of these excerpts would be found in the Go part of a section, into which the code from the section named "Empty the *buffer* array" is being spliced. The second excerpt would be found in the TEX part of the section, and the named section is being "cited", rather than defined or used. (Note the '|...|' surrounding the section name in this case.)

Strings and constants

If you want a string to appear in the Go file, delimited by pairs of ' or " marks as usual, you can type it exactly so in the GOWEB file, except that the character '@' should be typed '@@' (it becomes a control code, the only one that can appear in strings; see below). Strings should end on the same line as they begin, unless there's a backslash at the end of lines within them.

TEX and Go have different ways to refer to octal and hex constants, because TEX is oriented to technical writing while Go is oriented to computer processing. In TEX you make a constant octal or hexadecimal by prepending ' or ", respectively, to it; in Go the constant should be preceded by 0 or 0x. In GOWEB it seems reasonable to let each convention hold in its respective realm; so in Go text you get 40_8 by typing '040', which GOTANGLE faithfully copies into the Go file (for the compiler's benefit) and which GOWEAVE prints as $^\circ 40$. Similarly, GOWEAVE prints the hexadecimal Go constant '0x20' as $^\#20$. The use of italic font for octal digits and typewriter font for hexadecimal digits makes the meaning of such constants clearer in a document. For consistency, then, you should type '|040|' or '|0x20|' in the TEX part of the section.

Control codes

A GOWEB *control code* is a two-character combination of which the first is '@'. We've already seen the meaning of several control codes; it's time to list them more methodically.

In the following list, the letters in brackets after a control code indicate in what contexts that code is allowed. *L* indicates that the code is allowed in limbo; *T* (for TEX), *M* (for middle), and *C* (for Go code) mean that the code is allowed in each of the three parts of a section, at top level—that is, outside such constructs as '|...|' and section names. An arrow $\rightarrow$ means that the control code terminates the present part of the GOWEB file, and inaugurates the part indicated by the letter following the arrow. Thus $[LTMC \rightarrow T]$ next to @␣ indicates that this control code can occur in limbo, or in any of the three parts of a section, and that it starts the (possibly empty) TEX part of the following section.

Two other abbreviations can occur in these brackets: The letter r stands for *restricted context*, that is, material inside Go comments, section names, Go strings and control texts (defined below); the letter c stands for *inner* Go *context*, that is, Go material inside '`|...|`' (including '`|...|`'s inside comments, but not those occurring in other restricted contexts). An asterisk $*$ following the brackets means that the context from this control code to the matching `@>` is restricted.

Control codes involving letters are case-insensitive; thus `@c` and `@C` are equivalent. Only the lowercase versions are mentioned specifically below.

`@@` $[LTMCrc]$ A double `@` denotes the single character '`@`'. This is the only control code that is legal everywhere. Note that you must use this convention if you are giving an internet email address in a GOWEB file (e.g., `levy@@math.berkeley.edu`).

Here are the codes that introduce the TEX part of a section.

`@␣` $[LTMC \to T]$ This denotes the beginning of a new (unstarred) section. A tab mark or form feed or end-of-line character is equivalent to a space when it follows an `@` sign (and in most other cases).

`@*` $[LTMC \to T]$ This denotes the beginning of a new starred section, i.e., a section that begins a new major group. The title of the new group should appear after the `@*`, followed by a period. As explained above, TEX control sequences should be avoided in such titles unless they are quite simple. When GOWEAVE and GOTANGLE read a `@*`, they print an asterisk on the terminal followed by the current section number, so that the user can see some indication of progress. The very first section should be starred.

You can specify the "depth" of a starred section by typing `*` or a decimal number after the `@*`; this indicates the relative ranking of the current group of sections in the program hierarchy. Top-level portions of the program, introduced by `@**`, get their names typeset in boldface type in the table of contents; they are said to have depth -1. Otherwise the depth is a nonnegative number, which governs the amount of indentation on the contents page. Such indentation helps clarify the structure of a long program. The depth is assumed to be 0 if it is not specified explicitly; when your program is short, you might as well leave all depths zero. A starred section always begins a new page in the output, unless the depth is greater than 1.

The middle part of each section consists of any number of format definitions (beginning with `@f` or `@s`), intermixed in any order.

`@f` $[TM \to M]$ Format definitions begin with `@f`; they cause GOWEAVE to treat identifiers in a special way when they appear in Go text. The general form of a format definition is '`@f` l r', followed by an optional comment enclosed between `/*` and `*/`, where l and r are identifiers; GOWEAVE will subsequently treat identifier l as it currently treats r. This feature allows a GOWEB programmer to invent new reserved words and/or to unreserve some of Go's reserved identifiers. For example, the common word 'error' has been given a special meaning in the Go, so GOWEAVE is set up to format them specially; if you want a variable named *error*, you should say

```
@f error normal
```

somewhere in your program.

If r is the special identifier '*TeX*', identifier l will be formatted as a TEX control sequence; for example, '`@f foo TeX`' in the GOWEB file will cause identifier *foo* to be output as `\foo` by GOWEAVE. The programmer should define `\foo` to have whatever custom format is desired, assuming TEX math mode. (Each underline character is converted to `x` when making the TEX control sequence, and each dollar sign is converted to `X`; thus *foo_bar* becomes `\fooxbar`. Other characters, including digits, are left untranslated, so TEX will consider them as macro parameters, not as part of the control sequence itself. For example,

```
\def\x#1{x_{#1}} @f x1 TeX @f x2 TeX
```

will format `x1` and `x2` not as *x1* and *x2* but as x_1 and x_2.)

If r is the special identifier '*make_pair*', identifier l will be treated as a C++ function template. For example, after `@f convert make_pair` one can say '`convert<int>(2.5)`' without having `<` and `>` misunderstood as less-than and greater-than signs.

`@s` $[TM \to M;\ L]$ Same as `@f`, but GOWEAVE does not show the format definition in the output, and the optional Go comment is not allowed. This is used mostly in `@i` files.

Next come the codes that govern the Go part of a section.

`@c` `@p` $[TM \to C]$ The Go part of an unnamed section begins with `@c` for "code" (or with `@p` for "program"; both control codes do the same thing). This causes GOTANGLE to append the following Go code to the first-order program text, as explained on page 3. Note that GOWEAVE does not print a '`@c`' in the TEX output, so if you are creating a GOWEB file based on a TEX-printed GOWEB documentation you have to remember to insert `@c` in the appropriate places of the unnamed sections.

`@<` $[TM \to C;\ C;\ c]$ $*$ This control code introduces a section name (or unambiguous prefix, as discussed above), which consists of TEX text and extends to the matching `@>`. The whole construct `@<...@>` is conceptually a Go element. The behavior is different depending on the context:

A `@<` appearing in contexts T and M attaches the following section name to the current section, and inaugurates the Go part of the section. The closing `@>` should be followed by `=` or `+=`.

In context C, `@<` indicates that the named section is being used—its Go definition is spliced in by GOTANGLE, as explained on page 3. As an error-detection measure, GOTANGLE and GOWEAVE complain if such a section name is followed by `=`, because most likely this is meant as the definition of a new section, and so should be preceded by `@␣`. If you really want to say $\langle\,\text{foo}\,\rangle = \mathit{bar}$, where $\langle\,\text{foo}\,\rangle$ is being used and not defined, put a newline before the `=`.

Finally, in inner Go context (that is, within '`|...|`' in the TEX part of a section or in a comment), `@<...@>` means that the named section is being cited. Such an occurrence is ignored by GOTANGLE. Note that even here we think of the section name as being a Go element, hence the `|...|`.

`@(` $[TM \to C;\ C;\ c]$ $*$ A section name can begin with `@(`. Everything works just as for `@<`, except that the Go code of the section named `@(foo@>` is written by GOTANGLE to file `foo`. In this way you can get multiple-file output from a single GOWEB file. One use of this feature is to produce header files for other program modules that will be loaded with the present one. Another use is to produce a test routine that goes with your program. By keeping the sources for a program and its header and test routine together, you are more likely to keep all three consistent with each other. Notice that the output of a named section can be incorporated in several different output files, because you can mention `@<foo@>` in both `@(bar1@>` and `@(bar2@>`.

The next several control codes introduce "control texts," which end with the next '`@>`'. The closing '`@>`' must be on the same line of the GOWEB file as the line where the control text began. The context from each of these control codes to the matching `@>` is restricted.

`@^` $[TMCc]$ $*$ The control text that follows, up to the next '`@>`', will be entered into the index together with the identifiers of the Go program; this text will appear in roman type. For example, to put the phrase "system dependencies" into the index that is output by GOWEAVE, type '`@^system dependencies@>`' in each section that you want to index as system dependent.

`@.` $[TMCc]$ $*$ The control text that follows will be entered into the index in `typewriter type`.

`@:` $[TMCc]$ $*$ The control text that follows will be entered into the index in a format controlled by the TEX macro '`\9`', which you should define as desired.

`@t` $[MCc]$ $*$ The control text that follows will be put into a TEX `\hbox` and formatted along with the neighboring Go program. This text is ignored by GOTANGLE, but it can be used for various purposes within GOWEAVE. For example, you can make comments that mix Go and classical mathematics, as in '$\mathit{size} < 2^{15}$', by typing '`|size < 2@t$^{15}$@>|`'.

`@=` $[MCc]$ $*$ The control text that follows will be passed verbatim to the Go program.

`@q` $[LTMCc]$ $*$ The control text that follows will be totally ignored—it's a comment for readers of the GOWEB file only. A file intended to be included in limbo, with `@i`, can identify itself with `@q` comments. Another use is to balance unbalanced parentheses in Go strings, so that your text editor's parenthesis matcher doesn't go into a tailspin.

`@!` $[TMCc]$ $*$ The section number in an index entry will be underlined if '`@!`' immediately precedes the identifier or control text being indexed. This convention is used to distinguish the sections where an identifier is defined, or where it is explained in some special way, from the sections where it is used. A reserved word or an identifier of length one will not be indexed except for underlined entries. An '`@!`' is implicitly inserted by GOWEAVE when an identifier is being defined or declared in Go code; for example, the definition

$$\textbf{int}\ \mathit{array}[\mathit{max\_dim}],\ \mathit{count} = \mathit{old\_count};$$

makes the names *array* and *count* get an underlined entry in the index. Statement labels, function definitions like *main*(**int** *argc*, **char** ∗*argv*[]), and **typedef** definitions also imply underlining. An old-style function definition (without prototyping) doesn't define its arguments; the arguments will, however, be considered to be defined (i.e., their index entries will be underlined) if their types are declared before the body of the function in the usual way (e.g., '**int** *argc*; **char** ∗*argv*[]; {...}'). Thus `@!` is not needed very often, except in unusual constructions or in cases like

```
enum boolean {@!false, @!true};
```

here `@!` gives the best results because individual constants enumerated by `enum` are not automatically underlined in the index at their point of definition.

We now turn to control codes that affect only the operation of `GOTANGLE`.

`@&` [*MCc*] The `@&` operation causes whatever is on its left to be adjacent to whatever is on its right, in the Go output. No spaces or line breaks will separate these two items.

`GOWEAVE` passes all characters straight through to TEX without transliteration; therefore TEX must be prepared to receive them. If you are formatting all your nonstandard identifiers as "custom" control sequences, you should make TEX treat all their characters as letters. Otherwise you should either make your codes "active" in TEX, or load fonts that contain the special characters you need in the correct positions. (The font selected by TEX control sequence `\it` is used for identifiers.) Look for special macro packages designed for `GOWEB` users in your language; or, if you are brave, write one yourself.

The next eight control codes (namely '`@,`', '`@/`', '`@|`', '`@#`', '`@+`', '`@;`', '`@[`', and '`@]`') have no effect on the Go program output by `GOTANGLE`; they merely help to improve the readability of the TEX-formatted Go that is output by `GOWEAVE`, in unusual circumstances. `GOWEAVE`'s built-in formatting method is fairly good when dealing with syntactically correct Go text, but it is incapable of handling all possible cases, because it must deal with fragments of text involving macros and section names; these fragments do not necessarily obey Go's syntax. Although `GOWEB` allows you to override the automatic formatting, your best strategy is not to worry about such things until you have seen what `GOWEAVE` produces automatically, since you will probably need to make only a few corrections when you are touching up your documentation.

`@,` [*MCc*] This control code inserts a thin space in `GOWEAVE`'s output. Sometimes you need this extra space if you are using macros in an unusual way, e.g., if two identifiers are adjacent.

`@/` [*MC*] This control code causes a line break to occur within a Go program formatted by `GOWEAVE`. Line breaks are chosen automatically by TEX according to a scheme that works 99% of the time, but sometimes you will prefer to force a line break so that the program is segmented according to logical rather than visual criteria. If a comment follows, say '`@/@,`' to break the line before the comment.

`@|` [*MC*] This control code specifies an optional line break in the midst of an expression. For example, if you have a long expression on the right-hand side of an assignment statement, you can use '`@|`' to specify breakpoints more logical than the ones that TEX might choose on visual grounds.

`@#` [*MC*] This control code forces a line break, like `@/` does, and it also causes a little extra white space to appear between the lines at this break. You might use it, for example, between groups of macro definitions that are logically separate but within the same section. `GOWEB` automatically inserts this extra space between functions, between external declarations and functions, and between declarations and statements within a function.

`@+` [*MC*] This control code cancels a line break that might otherwise be inserted by `GOWEAVE`, e.g., before the word '**else**', if you want to put a short if–else construction on a single line. If you say '`{@+`' at the beginning of a compound statement that is the body of a function, the first declaration or statement of the function will appear on the same line as the left brace, and it will be indented by the same amount as the second declaration or statement on the next line.

`@;` [*MC*] This control code is treated like a semicolon, for formatting purposes, except that it is invisible. You can use it, for example, after a section name or macro when the Go text represented by that section is a compound statement or ends with a semicolon. Consider constructions like

```
if condition { expresson @; } else { break; }
```

where *expresson* is defined to be a compound statement (enclosed in braces).

The remaining control codes govern the input that GOWEB sees.

`@x @y @z` [*change_file*] GOWEAVE and GOTANGLE are designed to work with two input files, called *web_file* and *change_file*, where *change_file* contains data that overrides selected portions of *web_file*. The resulting merged text is actually what has been called the GOWEB file elsewhere in this report.

Here's how it works: The change file consists of zero or more "changes," where a change has the form '`@x`⟨old lines⟩`@y`⟨new lines⟩`@z`'. The special control codes `@x`, `@y`, `@z`, which are allowed only in change files, must appear at the beginning of a line; the remainder of such a line is ignored. The ⟨old lines⟩ represent material that exactly matches consecutive lines of the *web_file*; the ⟨new lines⟩ represent zero or more lines that are supposed to replace the old. Whenever the first "old line" of a change is found to match a line in the *web_file*, all the other lines in that change must match too.

Between changes, before the first change, and after the last change, the change file can have any number of lines that do not begin with '`@x`', '`@y`', or '`@z`'. Such lines are bypassed and not used for matching purposes.

This dual-input feature is useful when working with a master GOWEB file that has been received from elsewhere (e.g., `tangle.w` or `weave.w` or `tex.web`), when changes are desirable to customize the program for your local computer system. You will be able to debug your system-dependent changes without clobbering the master web file; and once your changes are working, you will be able to incorporate them readily into new releases of the master web file that you might receive from time to time.

`@i` [*web_file*] Furthermore the *web_file* itself can be a combination of several files. When either GOWEAVE or GOTANGLE is reading a file and encounters the control code `@i` at the beginning of a line, it interrupts normal reading and starts looking at the file named after the `@i`, much as the Go preprocessor does when it encounters an `#include` line. After the included file has been entirely read, the program goes back to the next line of the original file. The file name following `@i` can be surrounded by `"` characters, but such delimiters are optional. Include files can nest.

Change files can have lines starting with `@i`. In this way you can replace one included file with another. Conceptually, the replacement mechanism described above does its work first, and its output is then checked for `@i` lines. If `@i foo` occurs between `@y` and `@z` in a change file, individual lines of file `foo` and files it includes are not changeable; but changes can be made to lines from files that were included by unchanged input.

On UNIX systems (and others that support environment variables), if the environment variable `GOWEBINPUTS` is set, GOWEB will look for include files in the colon separated directories thus named, if it cannot find them in the current directory.

Additional features and caveats

1. In certain installations of GOWEB that have an extended character set, the characters ←, ≠, ≤, ≥, ≡, ∨ and ∧ can be typed as abbreviations for '`<-`', '`!=`', '`<=`', '`>=`', '`==`', '`||`' and '`&&`', respectively.

3. The TEX file output by GOWEAVE is broken into lines having at most 80 characters each. When TEX text is being copied, the existing line breaks are copied as well. If you aren't doing anything too tricky, GOWEAVE will recognize when a TEX comment is being split across two or more lines, and it will append '`%`' to the beginning of such continued comments.

4. Go text is translated by a "bottom up" procedure that identifies each token as a "part of speech" and combines parts of speech into larger and larger phrases as much as possible according to a special grammar that is explained in the documentation of GOWEAVE. It is easy to learn the translation scheme for simple constructions like single identifiers and short expressions, just by looking at a few examples of what GOWEAVE does, but the general mechanism is somewhat complex because it must handle much more than Go itself. Furthermore the output contains embedded codes that cause TEX to indent and break lines as necessary, depending on the fonts used and the desired page width. For best results it is wise to avoid enclosing long Go texts in `|...|`, since the indentation and line breaking codes are omitted when the `|...|` text is translated from Go to TEX. Stick to simple expressions or statements. If a Go preprocessor command is enclosed in `|...|`, the `#` that introduces it must be at the beginning of a line, or GOWEAVE won't print it correctly.

5. Comments are not permitted in `|...|` text. After a '`|`' signals the change from TEX text to Go text, the next '`|`' that is not part of a string or control text or section name ends the Go text.

6. A comment must have properly nested occurrences of left and right braces, otherwise GOWEAVE will complain. But it does try to balance the braces, so that TEX won't foul up too much.

7. When you're debugging a program and decide to omit some of your Go code, do NOT simply "comment it out." Such comments are not in the spirit of GOWEB documentation; they will appear to readers as if they were explanations of the uncommented-out instructions. Furthermore, comments of a program must be valid TEX text; hence GOWEAVE will get confused if you enclose Go statements in `/*...*/` instead of in `/*|...|*/`.

8. The `@f` feature allows you to define one identifier to act like another, and these format definitions are carried out sequentially. In general, a given identifier has only one printed format throughout the entire document, and this format is used even before the `@f` that defines it. The reason is that GOWEAVE operates in two passes; it processes `@f`'s and cross-references on the first pass and it does the output on the second. (However, identifiers that implicitly get a boldface format, thanks to a `typedef` declaration, don't obey this rule; they are printed differently before and after the relevant `typedef`. This is unfortunate, but hard to fix. You can get around the restriction by saying, say, '`@s foo int`', before or after the `type`.)

9. Sometimes it is desirable to insert spacing into formatted Go code that is more general than the thin space provided by '`@,`'. The `@t` feature can be used for this purpose; e.g., '`@t\hskip 1in@>`' will leave one inch of blank space. Furthermore, '`@t\4@>`' can be used to backspace by one unit of indentation, since the control sequence `\4` is defined in `gowebmac` to be such a backspace. (This control sequence is used, for example, at the beginning of lines that contain labeled statements, so that the label will stick out a little at the left.) You can also use '`@t}\3{-5@>`' to force a break in the middle of an expression.

10. Each identifier in GOWEB has a single formatting convention. Therefore you shouldn't use the same identifier to denote, say, both a type name and part of a `struct`, even though Go does allow this.

Running the programs

The UNIX command line for GOTANGLE is

```
gotangle [options] web_file[.w] [{change_file[.ch]|-} [out_file]]
```

and the same conventions apply to GOWEAVE. If '`-`' or no change file is specified, the change file is null. The extensions `.w` and `.ch` are appended only if the given file names contain no dot. If the web file defined in this way cannot be found, the extension `.web` will be tried. For example, '`goweave cob`' will try to read `cob.w`; failing that, it will try `cob.web` before giving up. If no output file name is specified, the name of the Go file output by GOTANGLE is obtained by appending the extension `.c`; the name of the TEX file output by GOWEAVE gets the extension `.tex`. Index files output by GOWEAVE replace `.tex` by `.idx` and `.scn`.

Programmers who like terseness might choose to set up their operating shell so that '`wv`' expands to '`goweave -bhp`'; this will suppress most terminal output from GOWEAVE except for error messages.

Options are introduced either by a `-` sign, to turn an option off, or by a `+` sign to turn one on. For example, '`-fb`' turns off options `f` and `b`; '`+s`' turns on option `s`. Options can be specified before the file names, after the file names, or both. The following options are currently implemented:

`b` Print a banner line at the beginning of execution. (On by default.)

`c` Mark changed sections by '*' and show a list of the changed sections in the index. (On by default.) (Has no effect on GOTANGLE.)

`e` Enclose Go material formatted by GOWEAVE in brackets `\PB{...}`, so that special hooks can be used. (Off by default; has no effect on GOTANGLE.)

`f` Force line breaks after each Go statement formatted by GOWEAVE. (On by default; `-f` saves paper but looks less Go-like to some people.) (Has no effect on GOTANGLE.)

`h` Print a happy message at the conclusion of a successful run. (On by default.)

`p` Give progress reports as the program runs. (On by default.)

`s` Show statistics about memory usage after the program runs to completion. (Off by default.) If you have large GOWEB files or sections, you may need to see how close you come to exceeding the capacity of GOTANGLE and/or GOWEAVE.

`x` Include indexes and a table of contents in the TEX file output by GOWEAVE. (On by default.) (Has no effect on GOTANGLE.)

Hypertext and hyperdocumentation

Many people have of course noticed analogies between GOWEB and the World Wide Web. The GOWEB macros are in fact set up so that the output of GOWEAVE can be converted easily into Portable Document Format, with clickable hyperlinks that can be read with Adobe's Acrobat Reader, using a widely available open-source

program called dvipdfm developed by Mark A. Wicks. After using GOWEAVE to convert cob.w into cob.tex, you can prepare and view a hypertext version of the program by giving the commands

```
tex "\let\pdf+ \input cob"
dvipdfm cob
acroread cob.pdf
```

instead of invoking TEX in the normal way. (Thanks to Hans Hagen, César Augusto Rorato Crusius, and Julian Gilbey for the macros that make this work.) Alternatively, thanks to Hàn Thế Thành and Andreas Scherer, you can generate cob.pdf in one step by simply saying 'pdftex cob'.

Appendices

As an example of a real program written in GOWEB, Appendix A contains an excerpt from the GOWEB program itself. The reader who examines the listings in this appendix carefully will get a good feeling for the basic ideas of GOWEB.

Appendix B is the file that sets TEX up to accept the output of GOWEAVE, and Appendix C discusses how to use some of those macros to vary the output formats.

A "long" version of this manual, which can be produced from the GOWEB sources via the UNIX command make fullmanual, also contains appendices D, E, and F, which exhibit the complete source code for GOTANGLE and GOWEAVE.

Appendix A: Excerpts from a GOWEB Program

This appendix consists of four listings. The first shows the GOWEB input that generated sections 12–15 of the file common.w, which contains routines common to GOWEAVE and GOTANGLE. Note that some of the lines are indented to show the program structure; the indentation is ignored by GOWEAVE and GOTANGLE, but users find that GOWEB files are quite readable if they have some such indentation.

The second and third listings show corresponding parts of the Go code output by GOTANGLE and of the corresponding TEX code output by GOWEAVE, when run on common.w. The fourth listing shows how that output looks when printed out.

```
@ Procedure |prime_the_change_buffer|
sets |change_buffer| in preparation for the next matching operation.
Since blank lines in the change file are not used for matching, we have
|change_limit==0 && !changing| if and only if
the change file is exhausted. This procedure is called only when
|changing| is true; hence error messages will be reported correctly.

@c
func prime_the_change_buffer() {
change_buffer=nil

And here's what the same excerpt looks like when typeset.

19. Procedure *prime_the_change_buffer* sets *change_buffer* in preparation for the next matching operation. Since blank lines in the change file are not used for matching, we have (*change_limit* $\equiv 0 \wedge \neg$*changing*) if and only if the change file is exhausted. This procedure is called only when *changing* is true; hence error messages will be reported correctly.

```
func prime_the_change_buffer(){
  change_buffer = nil
  ⟨ Skip over comment lines in the change file; return if end of file 21 ⟩
  ⟨ Skip to the next nonblank line; return if end of file 22 ⟩
  ⟨ Move buffer to change_buffer 23 ⟩
}
```

20.
```
⟨ Import packages 13 ⟩ +≡
  "unicode"
```

21. While looking for a line that begins with `@x` in the change file, we allow lines that begin with `@`, as long as they don't begin with `@y`, `@z`, or `@i` (which would probably mean that the change file is fouled up).

```
⟨ Skip over comment lines in the change file; return if end of file 21 ⟩ ≡
  for true {
    change_line++
    if err := input_ln(change_file); err ≠ nil {
      return
    }
    if len(buffer)⟨2 {
      continue
    }
    if buffer[0] ≠ '@' {
      continue
    }
    if unicode.IsUpper(buffer[1]) {
      buffer[1] = unicode.ToLower(buffer[1])
    }
    if buffer[1] ≡ 'x' {
      break
    }
    if buffer[1] ≡ 'y' ∨ buffer[1] ≡ 'z' ∨ buffer[1] ≡ 'i' {
      loc = 2
      err_print("! Missing @x in change file")
    }
  }
```

This code is used in section 19.

22. Here we are looking at lines following the `@x`.

```
⟨ Skip to the next nonblank line; return if end of file 22 ⟩ ≡
  for true {
    change_line++
    if err := input_ln(change_file); err ≠ nil {
      err_print("! Change file ended after @x")
      return
    }
    if len(buffer) ≠ 0 {
      break
    }
  }
```

This code is used in section 19.

23.

```
⟨ Move buffer to change_buffer 23 ⟩ ≡
  {
    change_buffer = buffer
    buffer = nil
  }
```

This code is used in sections 19 and 26.

Appendix B: The gowebmac.tex file

This is the file that extends "plain TEX" format in order to support the features needed by the output of GOWEAVE.

Appendix C: How to use GOWEB macros

The macros in `gowebmac` make it possible to produce a variety of formats without editing the output of `GOWEAVE`, and the purpose of this appendix is to explain some of the possibilities.

1. Four fonts have been declared in addition to the standard fonts of `PLAIN` format: You can say '`{\mc UNIX}`' to get UNIX in xmedium-size caps; you can say '`{\sc STUFF}`' to get STUFF in small caps; and you can select the largish fonts `\titlefont` and `\ttitlefont` in the title of your document, where `\ttitlefont` is a typewriter style of type. There are macros `\UNIX/` and `\GO/` to refer to UNIX and Go with medium-size caps.

2. When you mention an identifier in TEX text, you normally call it '`|identifier|`'. But you can also say '`\\{identifier}`'. The output will look the same in both cases, but the second alternative doesn't put *identifier* into the index, since it bypasses `GOWEAVE`'s translation from Go mode. In the second case you must put a backslash before each underline character in the identifier.

3. To get typewriter-like type, as when referring to '`GOWEB`',you can use the '`\.`' macro (e.g., '`\.{GOWEB}`'). In the argument to this macro you should insert an additional backslash before the symbols listed as 'special string characters' in the index to `GOWEAVE`, i.e., before backslashes and dollar signs and the like. A '`\␣`' here will result in the visible space symbol; to get an invisible space following a control sequence you can say '`{\␣}`'. If the string is long, you can break it up into substrings that are separated by '`\)`'; the latter gives a discretionary backslash if TEX has to break a line here.

4. The three control sequences `\pagewidth`, `\pageheight`, and `\fullpageheight` can be redefined in the limbo section at the beginning of your `GOWEB` file, to change the dimensions of each page. The default settings

```
\pagewidth=6.5in
\pageheight=8.7in
\fullpageheight=9in
```

were used to prepare this manual; `\fullpageheight` is `\pageheight` plus room for the additional heading and page numbers at the top of each page. If you change any of these quantities, you should call the macro `\setpage` immediately after making the change.

5. The `\pageshift` macro defines an amount by which right-hand pages (i.e., odd-numbered pages) are shifted right with respect to left-hand (even-numbered) ones. By adjusting this amount you may be able to get two-sided output in which the page numbers line up on opposite sides of each sheet.

6. The `\title` macro will appear at the top of each page in small caps; it is the job name unless redefined.

7. The first page usually is assigned page number 1. To start on page 16, with contents on page 15, say this: '`\def\contentspagenumber{15} \pageno=\contentspagenumber \advance\pageno by 1`'.

8. The macro `\iftitle` will suppress the header line if it is defined by '`\titletrue`'. The normal value is `\titlefalse` except for the table of contents; thus, the contents page is usually unnumbered.

Two macros are provided to give flexibility to the table of contents: `\topofcontents` is invoked just before the contents info is read, and `\botofcontents` is invoked just after. Here's a typical definition:

```
\def\topofcontents{\null\vfill
  \titlefalse % include headline on the contents page
  \def\rheader{\mainfont The {\tt GOWEAVE} processor\hfil}
  \centerline{\titlefont The {\ttitlefont GOWEAVE} processor}
  \vskip 15pt \centerline{(Version 3.64)} \vfill}
```

Redefining `\rheader`, which is the headline for right-hand pages, suffices in this case to put the desired information at the top of the contents page.

9. Data for the table of contents is written to a file that is read after the indexes have been TEXed; there's one line of data for every starred section. The file `common.toc` might look like this:

```
\ZZ {Introduction}{0}{1}{28}{}
\ZZ {The character set}{2}{5}{29}{}
```

and so on. The `\topofcontents` macro could redefine `\ZZ` so that the information appears in any desired format. (See also point 19 below.)

10. Sometimes it is necessary or desirable to divide the output of GOWEAVE into subfiles that can be processed separately. For example, the listing of TEX runs to more than 500 pages, and that is enough to exceed the capacity of many printing devices and/or their software. When an extremely large job isn't cut into smaller pieces, the entire process might be spoiled by a single error of some sort, making it necessary to start everything over.

Here's a safe way to break a woven file into three parts: Say the pieces are α, β, and γ, where each piece begins with a starred section. All macros should be defined in the opening limbo section of α, and copies of this TEX code should be placed at the beginning of β and of γ. In order to process the parts separately, we need to take care of two things: The starting page numbers of β and γ need to be set up properly, and the table of contents data from all three runs needs to be accumulated.

The gowebmac macros include two control sequences \contentsfile and \readcontents that facilitate the necessary processing. We include '\def\contentsfile{cont1}' in the limbo section of α, and we include '\def\contentsfile{cont2}' in the limbo section of β; this causes TEX to write the contents data for α and β into cont1.tex and cont2.tex. Now in γ we say

```
\def\readcontents{\input cont1 \input cont2 \input \contentsfile};
```

this brings in the data from all three pieces, in the proper order.

However, we still need to solve the page-numbering problem. One way to do it is to include the following in the limbo material for β:

```
\message{Please type the last page number of part 1: }
\read -1 to \temp \pageno=\temp \advance\pageno by 1
```

Then you simply provide the necessary data when TEX requests it; a similar construction is used at the beginning of γ.

This method can, of course, be used to divide a woven file into any number of pieces.

11. Sometimes it is nice to include things in the index that are typeset in a special way. For example, we might want to have an index entry for 'TEX'. GOWEAVE provides two simple ways to typeset an index entry (unless the entry is an identifier or a reserved word): '@^' gives roman type, and '@.' gives typewriter type. But if we try to typeset 'TEX' in roman type by saying, e.g., '@^\TeX@>', the backslash character gets in the way, and this entry wouldn't appear in the index with the T's.

The solution is to use the '@:' feature, declaring a macro that simply removes a sort key as follows:

```
\def\9#1{}
```

Now you can say, e.g., '@:TeX}{\TeX@>' in your GOWEB file; GOWEAVE puts it into the index alphabetically, based on the sort key, and produces the macro call '\9{TeX}{\TeX}' which will ensure that the sort key isn't printed.

A similar idea can be used to insert hidden material into section names so that they are alphabetized in whatever way you might wish. Some people call these tricks "special refinements"; others call them "kludges."

12. The control sequence \secno is set to the number of the section being typeset.

13. If you want to list only the sections that have changed, together with the index, put the command '\let\maybe=\iffalse' in the limbo section before the first section of your GOWEB file. It's customary to make this the first change in your change file.

This feature has a TEXnical limitation, however: You cannot use it together with control sequences like \proclaim or \+ or \newcount that plain TEX has declared to be '\outer', because TEX refuses to skip silently over such control sequences. One way to work around this limitation is to say

```
\fi \let\proclaim\relax \def\proclaim{...} \ifon
```

where \proclaim is redefined to be the same as usual but without an \outer qualification. (The \fi here stops the conditional skipping, and the \ifon turns it back on again.) Similarly,

```
\fi \newcount\n \ifon
```

is a safe way to use \newcount. Plain TEX already provides a non-outer macro \tabalign that does the

work of `\+`; you can say

```
\fi \let\+\tabalign \ifon
```

if you prefer the shorter notation `\+`.

14. To get output in languages other than English, redefine the macros `\A`, `\As`, `\ATH`, `\ET`, `\ETs`, `\Q`, `\Qs`, `\U`, `\Us`, `\ch`, `\fin`, `\con`, `\today`, `\datethis`, and `\datecontentspage`. GOWEAVE itself need not be changed.

15. Some output can be selectively suppressed with the macros `\noatl`, `\noinx`, `\nosecs`, `\nocon`.

16. All accents and special text symbols of plain TEX format will work in GOWEB documents just as they are described in Chapter 9 of *The TEXbook*, with one exception. The dot accent (normally `\.`) must be typed `\:` instead.

17. Several commented-out lines in `gowebmac.tex` are suggestions that users may wish to adopt. For example, one such line inserts a blank page if you have a duplex printer. Appendices D, E, and F of the complete version of this manual are printed using a commented-out option that substitutes '←' for '=' in the program listings. Looking at those appendices might help you decide which format you like better.

18. Andreas Scherer has contributed a macro called `\pdfURL` with which one can say things like the following, anywhere in the TEX parts or the Go comments of a GOWEB file:

```
You can send email to \pdfURL{the author}{mailto:andreas.scherer@@pobox.com}
or visit \pdfURL{his home page}{http://www.pobox.com/\TILDE/scherer}.
```

In a PDF document, the first argument will appear in blue as clickable text; the Acrobat reader, if correctly configured, will then redirect those links to the user's browser and open either the email client or the HTML viewer. In a hardcopy document, both arguments will be printed (`the second in parentheses and typewriter type`). Certain special characters in an Internet address need to be handled in a somewhat awkward way, so that GOWEAVE and/or TEX will not confuse them with formatting controls: Use `@@` for `@` and `\TILDE/` for `~` and `\UNDER/` for `_`.

19. PDF documents contain bookmarks that list all the major group titles in the table of contents, some of which will be subsidiary to others if the depth feature of `@*` has been used. Such bookmark entries are also known as "outlines." Moreover, the final group title, 'Names of the sections', can be opened up to list every section name; Acrobat users can therefore navigate easily to any desired section.

The macros of `gowebmac.tex` are careful to "sanitize" all the names that appear as bookmarks, by removing special characters and formatting codes that are inappropriate for the limited typographic capabilities of PDF outlines. For example, one section of GOWEAVE is named 'Cases for *case_like*', which is represented by the TEX code '`Cases for \PB{\\{case\_like}}`' in `goweave.tex`; its sanitized name is simply '`Cases for case_like`'. (When `.pdf` files are produced, the fifth parameter of every `\ZZ` in the `.toc` file is set to the sanitized form of the first parameter; see point 9 above and point 20 below.)

In general, sanitization removes TEX control sequences and braces, except for control sequences defined by GOWEB itself. Such a translation works most of the time, but you can override the defaults and obtain any translation that you want by using TEXnical tricks. For example, after

```
\sanitizecommand\foo{bar}
```

the control sequence `\foo` will sanitize to '`bar`'. And after

```
\def\kluj#1\\{foo}
```

the TEX code '`\kluj bar\\`' will print as 'foo' but sanitize to '`bar`', because the control sequences `\kluj` and `\\` are removed by sanitization.

20. Furthermore, group titles can be converted to an arbitrary sanitized text while also changing their form in running headlines, by using `\ifheader`. Consider, for example, a GOWEB source file that begins with the two lines

```
\def\klujj#1\\{\ifheader FOO\else foo\fi}
@*Chinese \klujj bar\.
```

This coding introduces a major group entitled '**Chinese foo**', with running headline 'CHINESE FOO' and table-of-contents entry 'Chinese foo'. The corresponding bookmark is, however, '`Chinese bar`'. And the corresponding `.toc` file entry is '`\ZZ {Chinese \klujj bar\\}{1}{1}{1}{Chinese bar}`'.
